

MEMO: Automated Fuel Depot Efficiency Tracking

To: Senior Manager

From: The DICEE Team lead

Date: Week 1

Re: A faster way to spot underperforming depots

What We Built

We created a small tool that automatically checks how each depot is performing against its production target. For every depot, it calculates an **efficiency score**; the percentage of the target that was actually produced and then labels the depot as **Normal** (90% or above), **Warning** (70–89%), or **Critical** (below 70%). Right now, it covers Nairobi, Nakuru, and Mombasa, and it can easily be expanded to every depot the company operates.

Why This Matters

Today, checking depot performance means someone manually pulling output numbers, comparing them to targets, and deciding which sites need attention. This works, but it is slow, easy to get wrong, and depends on whoever is doing the check that week. As more depots are added, manual review will not scale. Automating this calculation means every depot is measured the same way, every time, with no risk of a typo or a missed site.

How This Helps Us Move Faster

Because the tool checks every depot in seconds and instantly flags anything below target, problems surface immediately instead of at the end of a manual review cycle. A depot quietly slipping to 40% output like Nakuru in the current data gets tagged **Critical** right away, rather than being noticed days later during a routine report. This gives managers a head start on fixing issues, instead of finding out after the damage is already done.

Sample Result

Depot	output /Target	Efficiency	Status
Nairobi Depot	800/1000	80.0%	Warning
Nakuru Depot	400 / 1000	40.0%	Critical
Mombasa Depot	950 / 1000	95.0%	Normal

Recommended Next Step

The team recommends rolling this tool out first within **Plant/Depot Management**, since that team already owns target-setting and site performance reviews. Concretely: run the tool each morning before the daily operations huddle so any depot flagged **Warning** or **Critical** can be raised and assigned an owner on the spot rather than waiting for the weekly report. Over time, this could be connected directly to existing production data so it updates on its own, with no manual entry needed.
